

Integration and Evaluation of Operational Machine Learning Hydrological Forecasts in Reclamation Regions

Plain language summary:

The U.S. Bureau of Reclamation and Upstream Tech are partnering to implement & evaluate operational machine learning inflow forecasts across key basins in all of Reclamation regions. Forecasts are all up and running and will be evaluated over the next two years.

Reclamation's Facilitated Adoption Program

The USBR operates vital water infrastructure in the U.S. West and aims to enhance inflow forecasting for water supply, power, recreation, irrigation, and flood control.

Following a 2020-21 prize competition, Upstream Tech's HydroForecast was selected as a potential solution to improve short-term inflow forecasts.

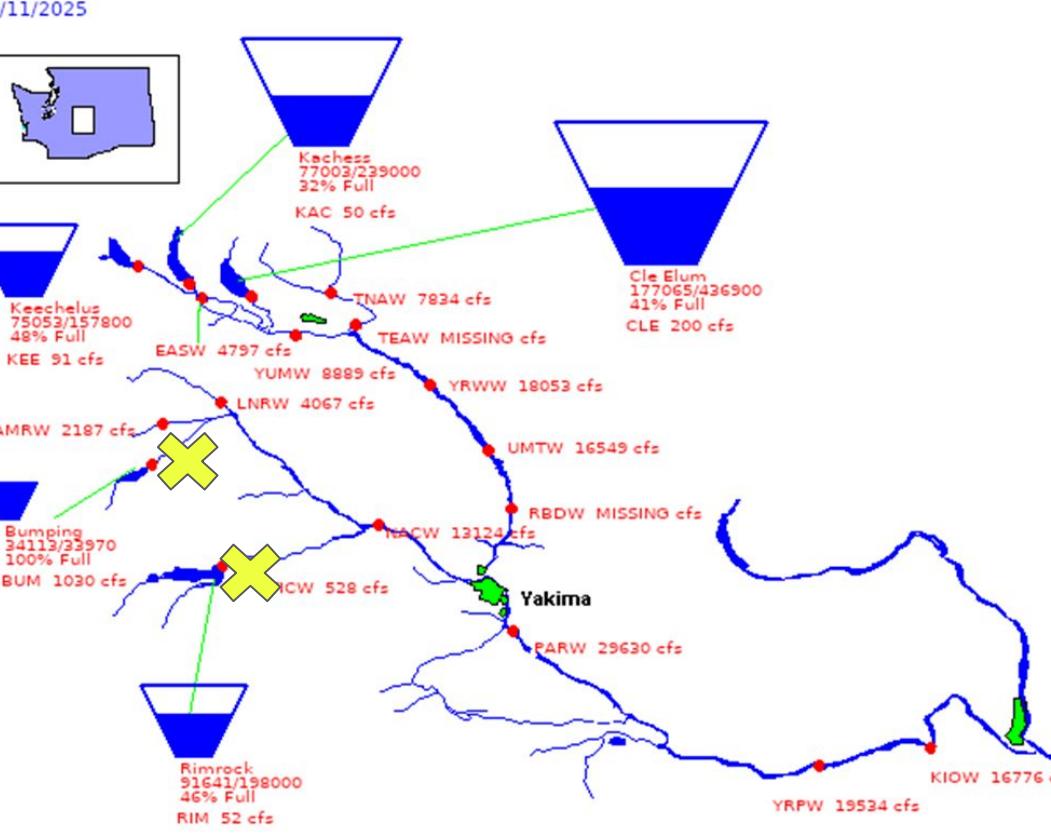

Geographic scope - 13 basins, 20 sites

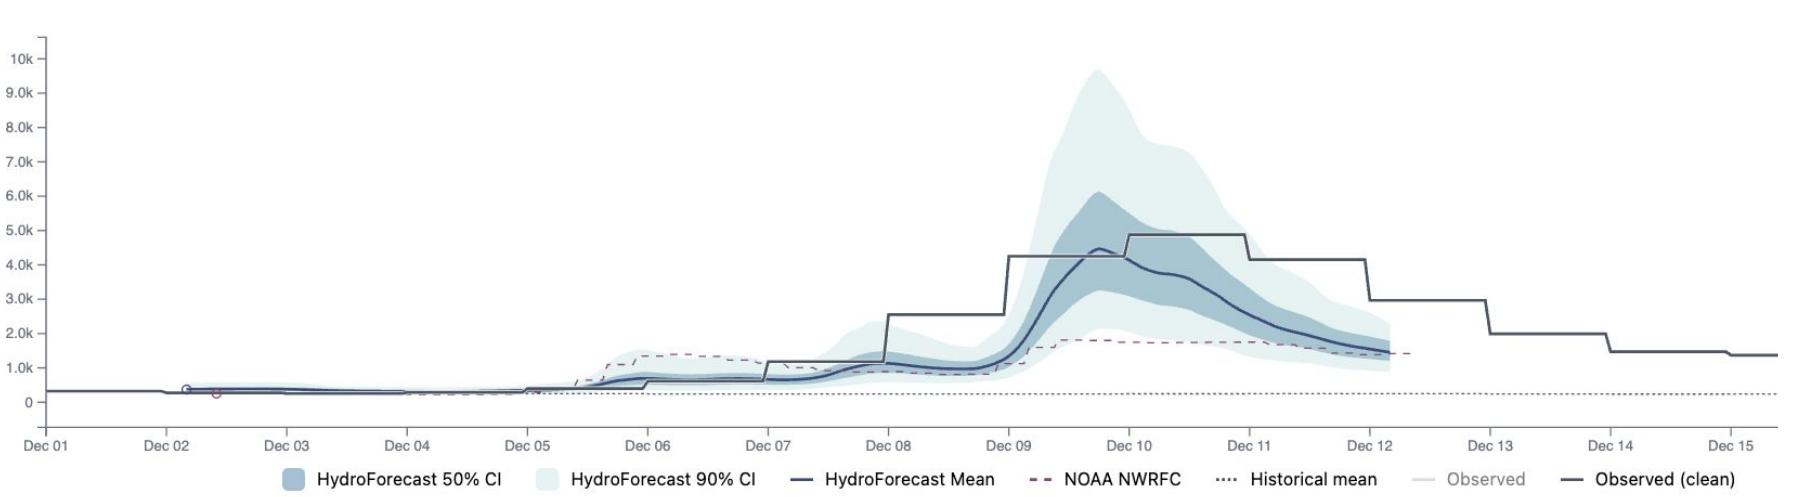

This Just In! Dec. 2025 Atmospheric River

Yakima River

Forecasts a week before the event indicated inflows exceeding reservoir storage capacity at one site and significant downstream flood risk.

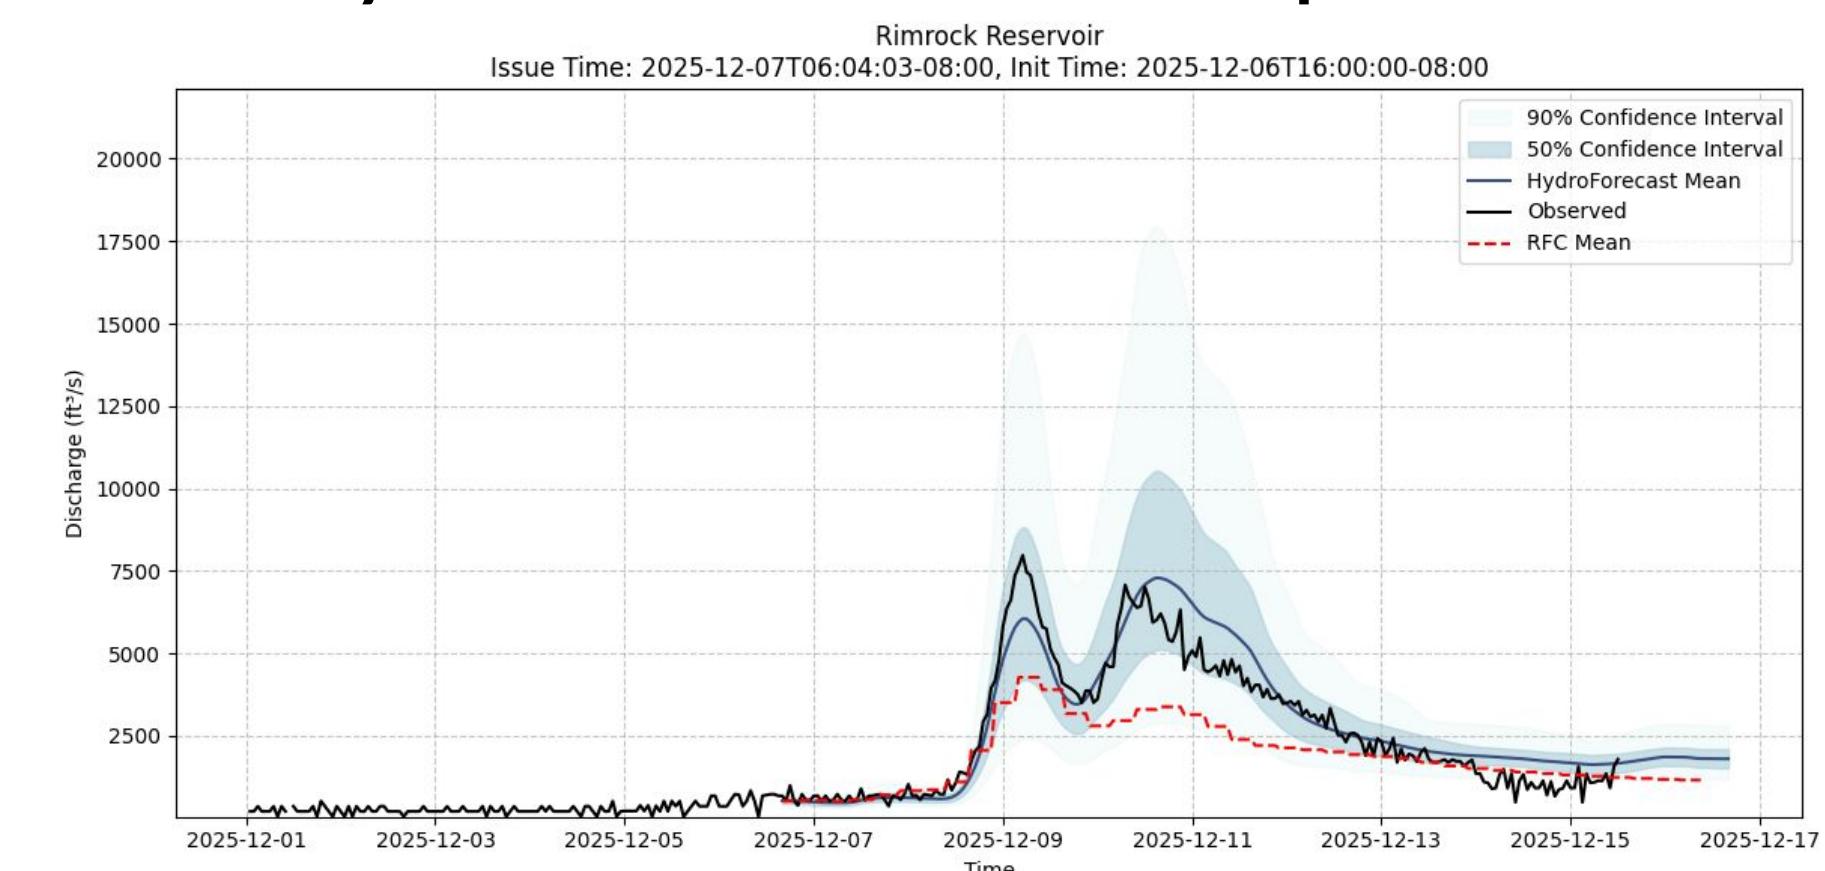

At Rimrock, forecasts issued 7 days ahead:

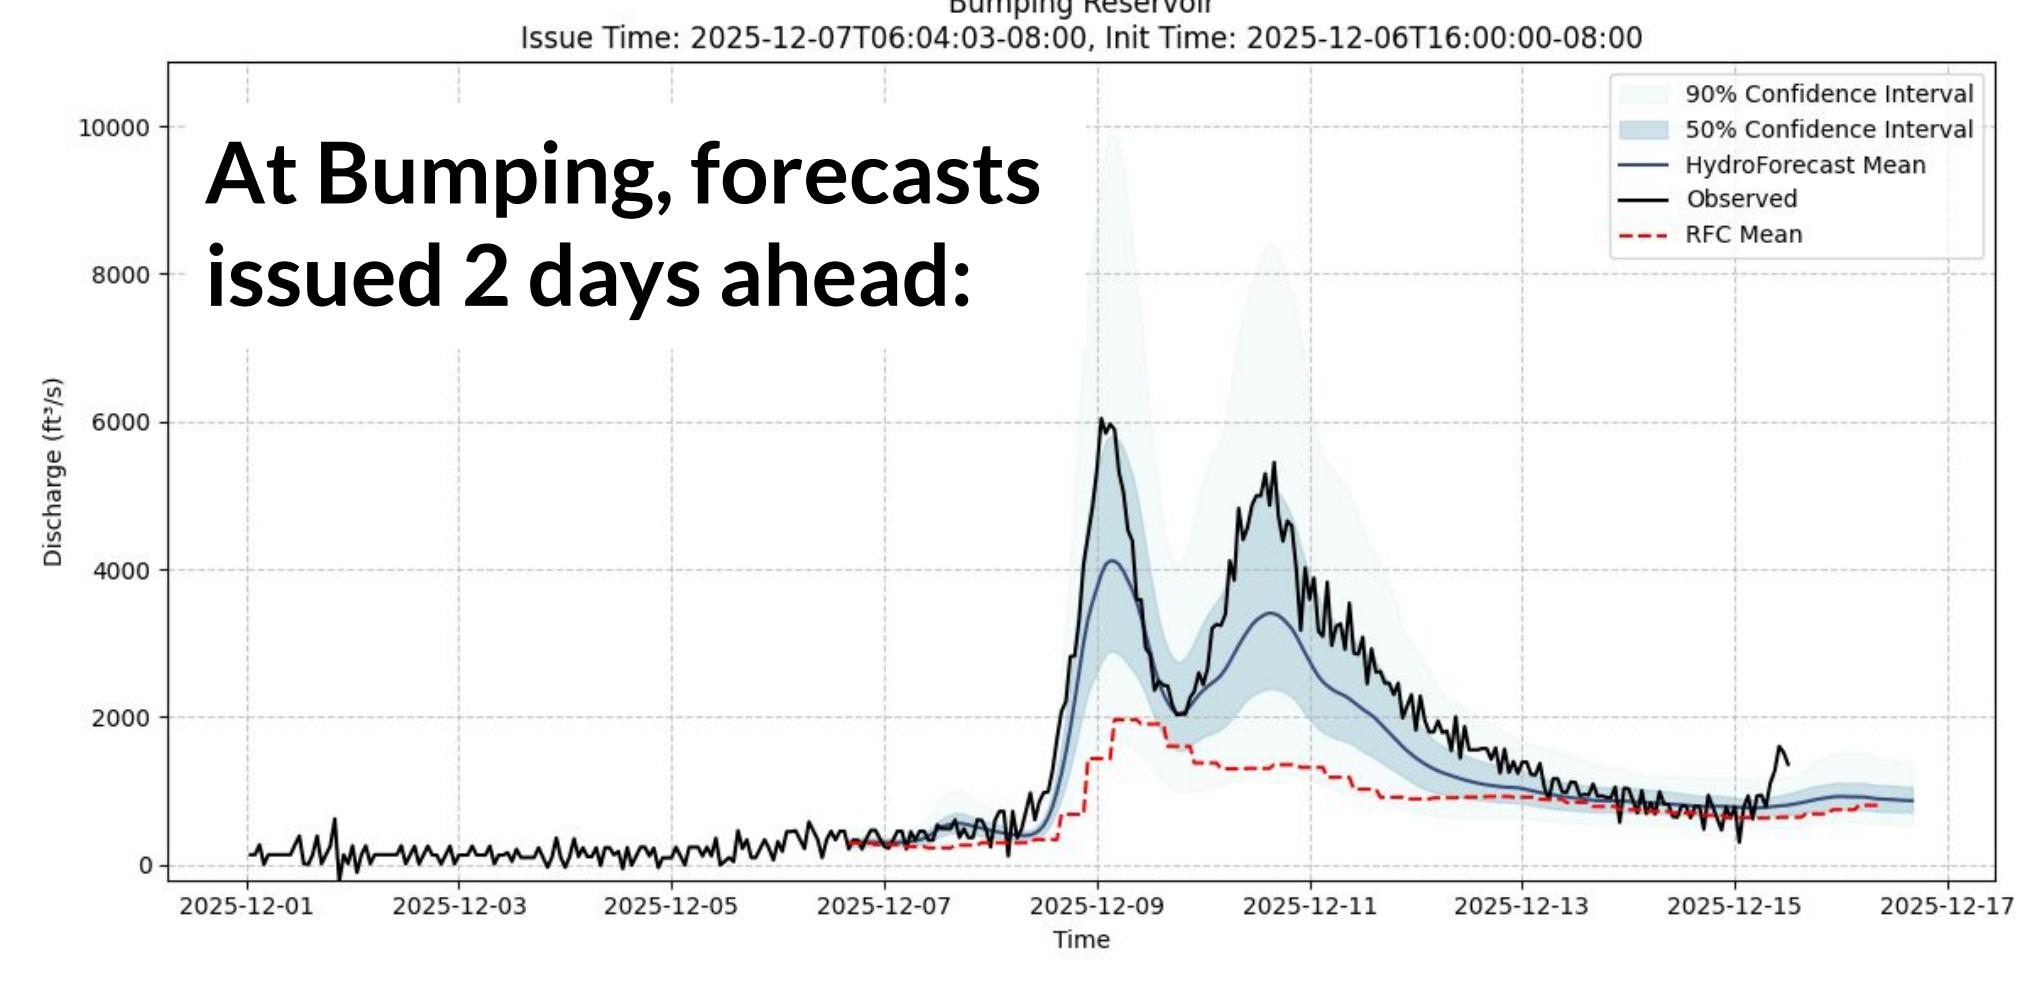

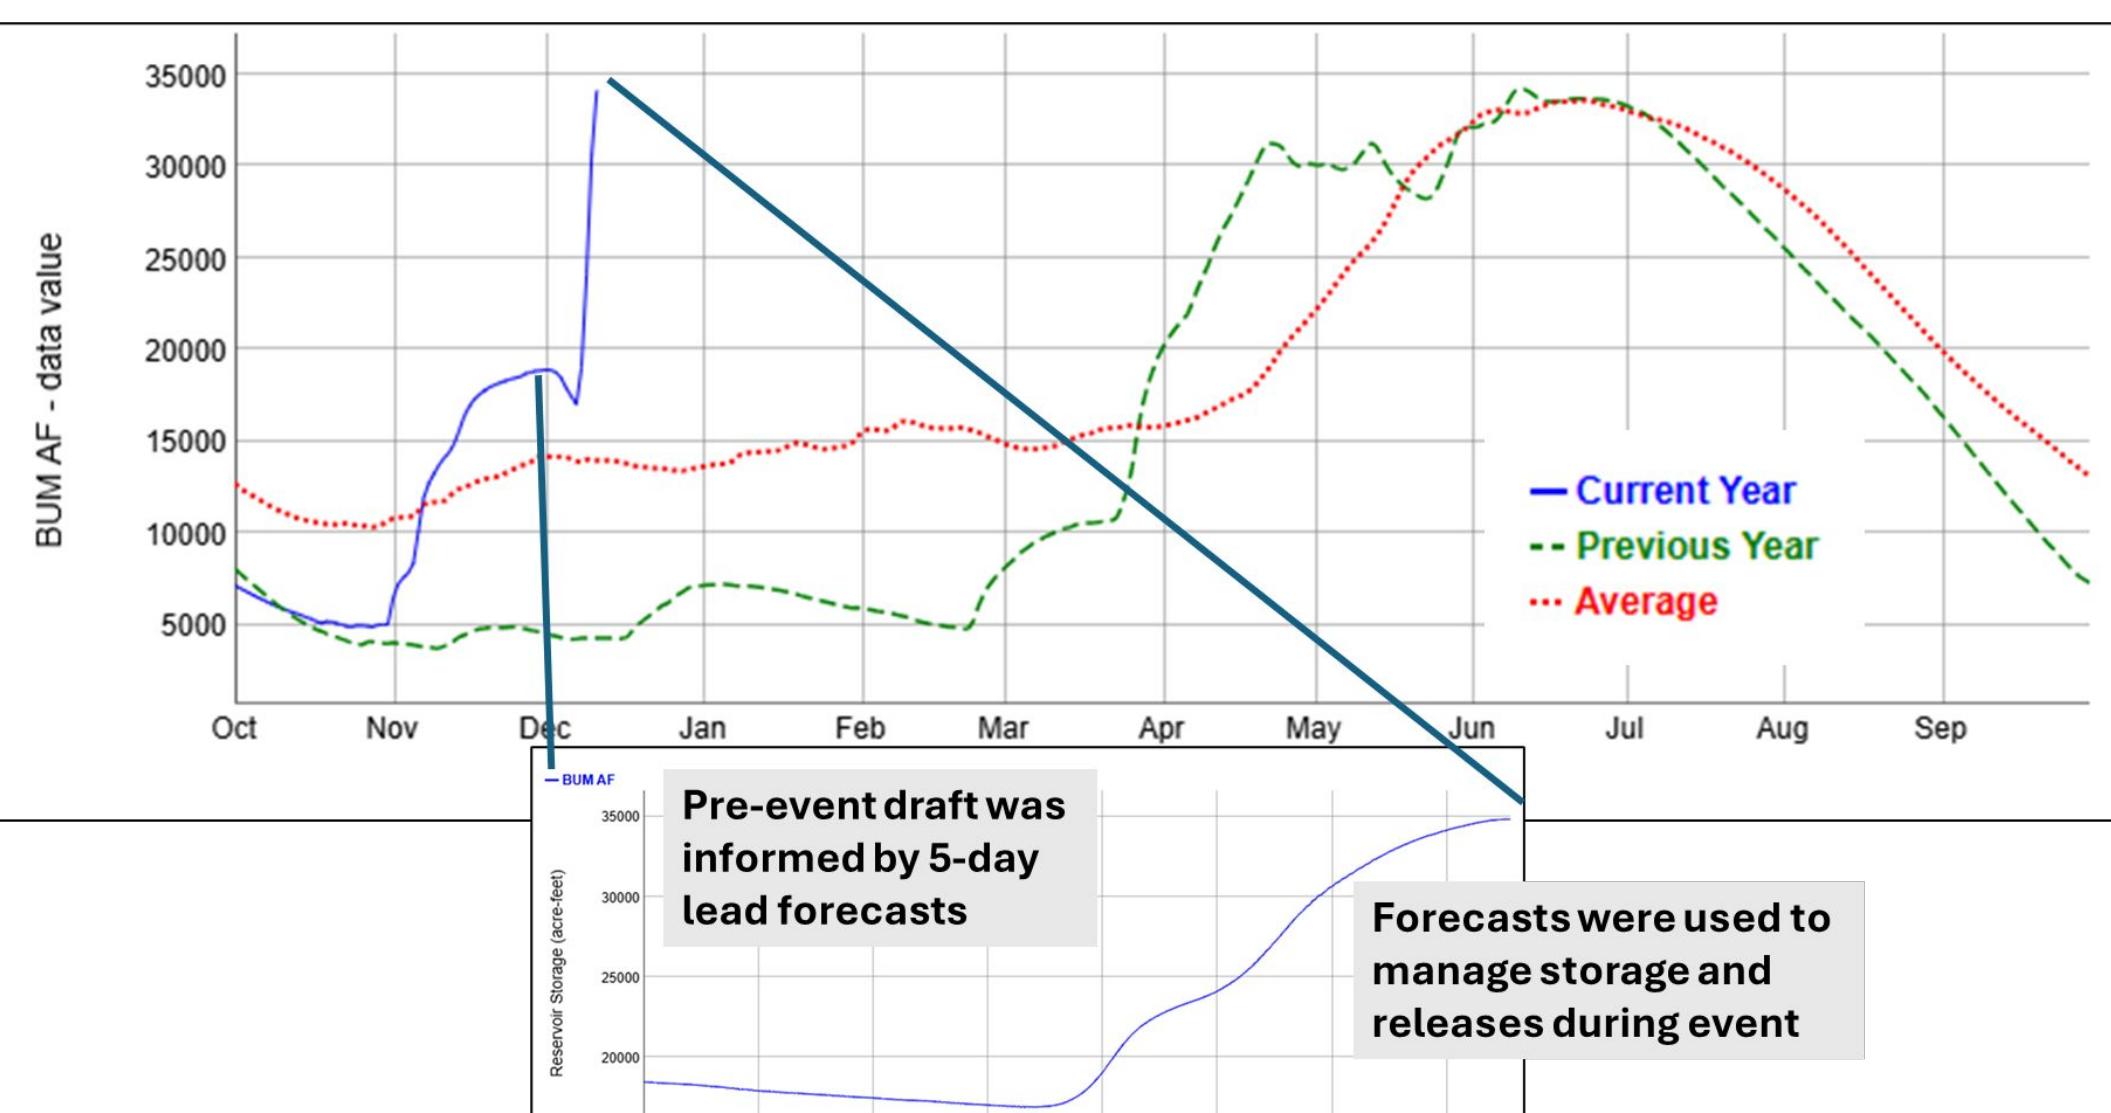

GEFS/GFS underpredicted total rain; HRRR and ECMWF were closer.

2-3 days ahead the double peak

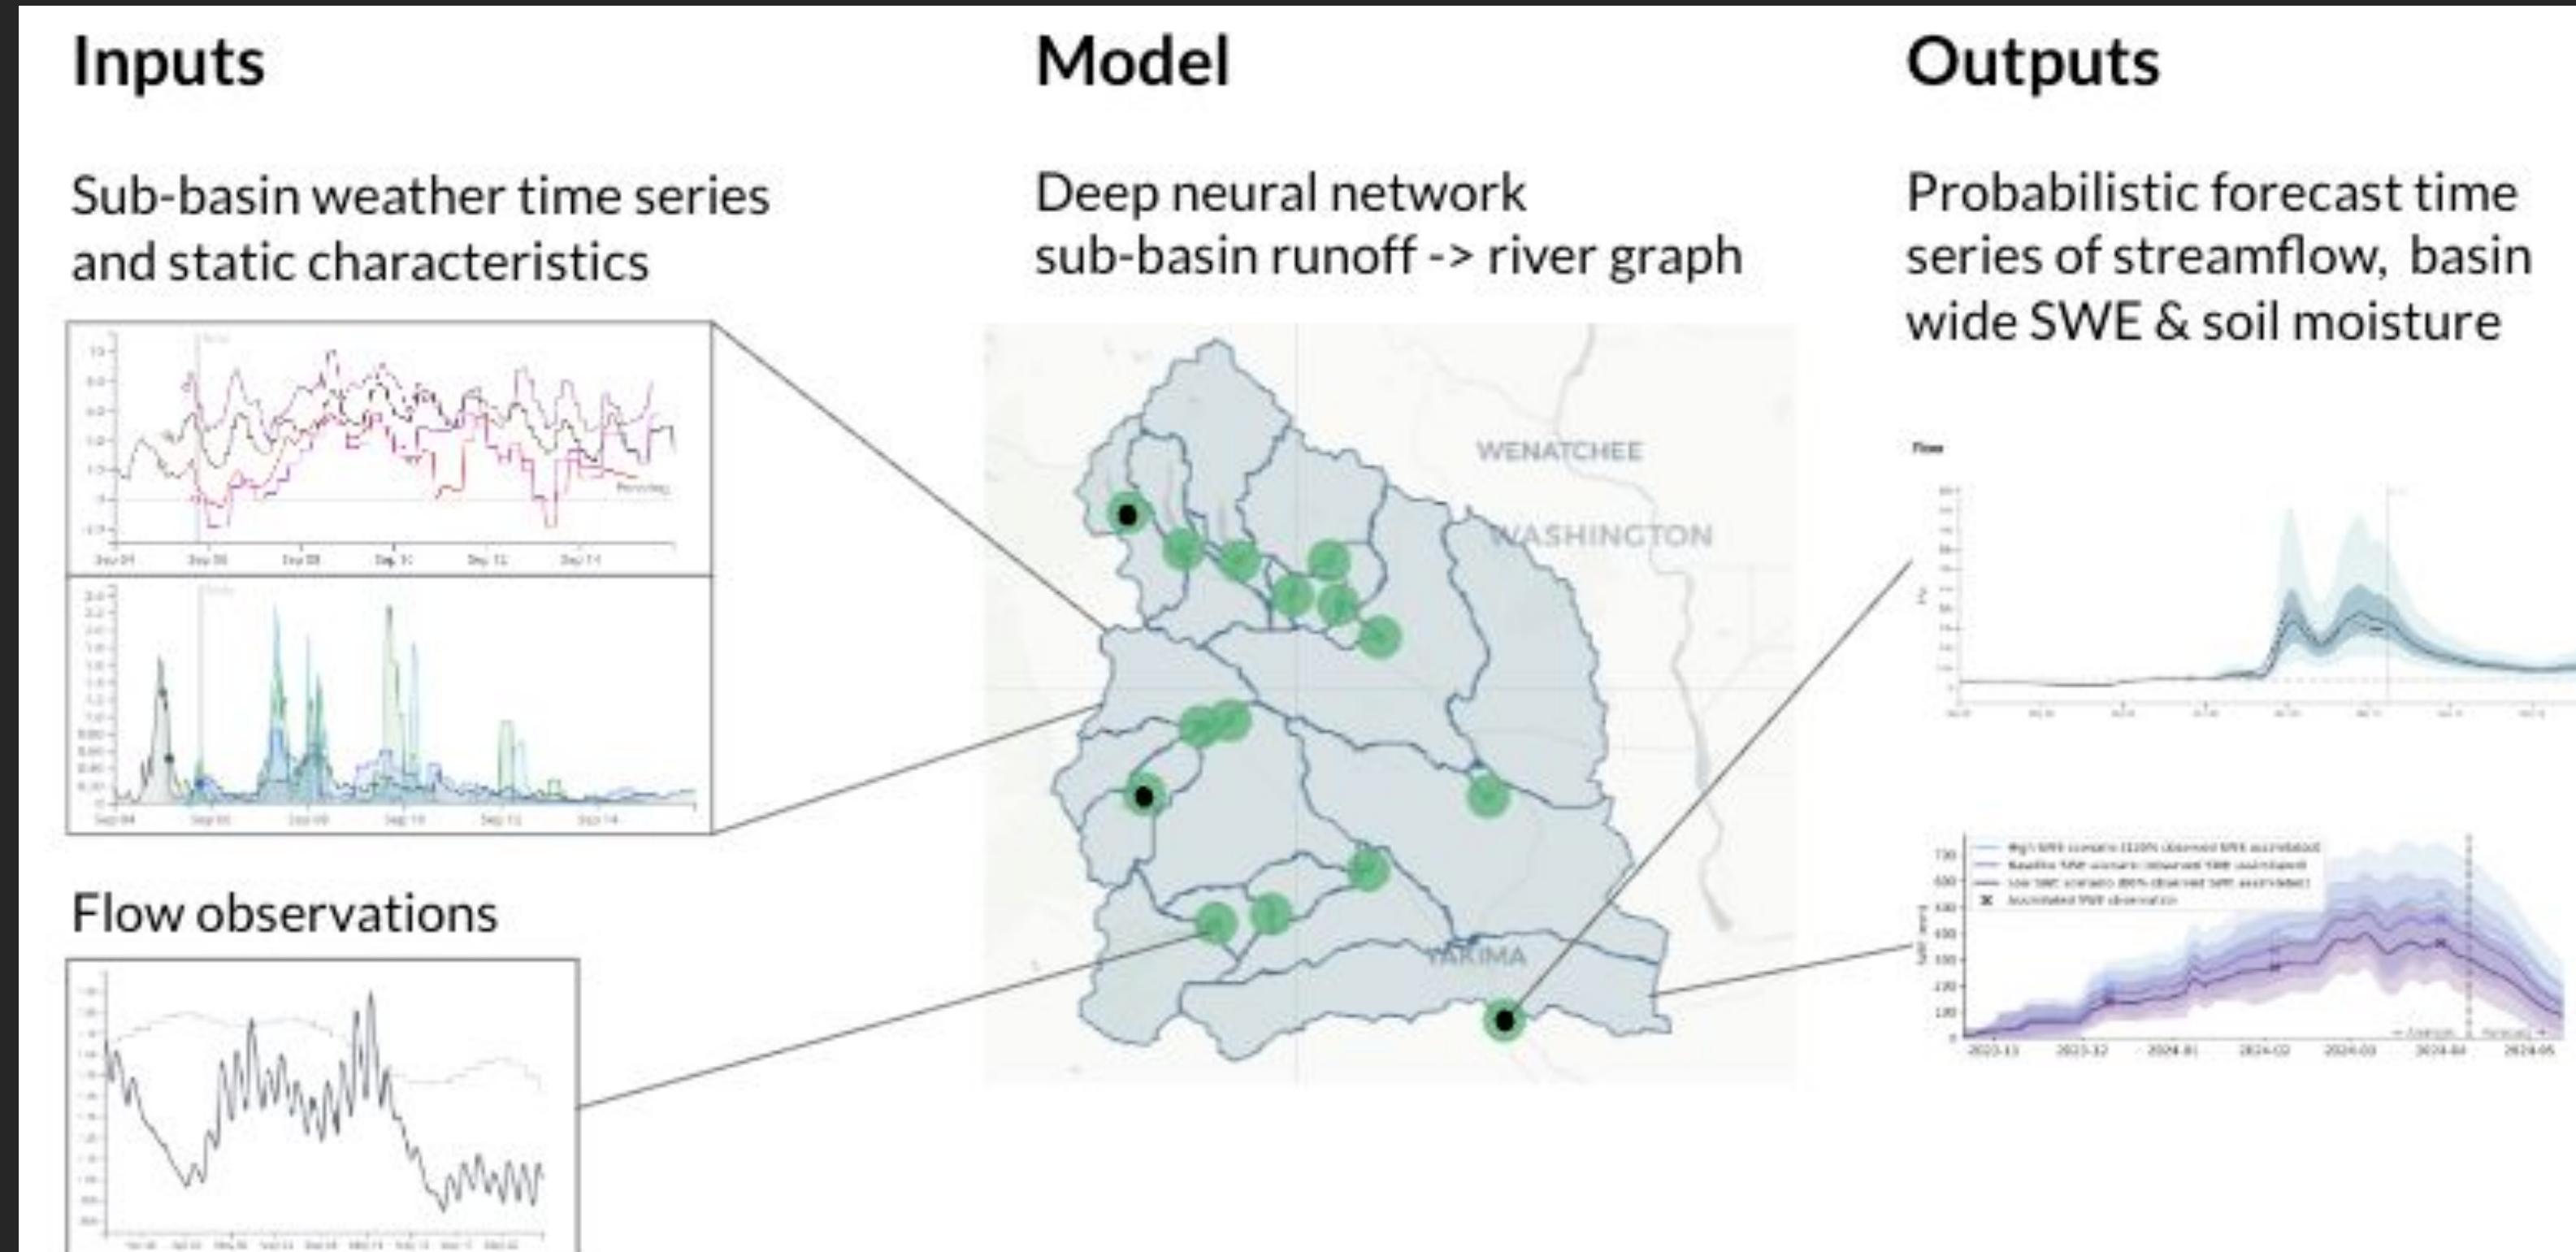

Bumping Reservoir Storage

What is HydroForecast?

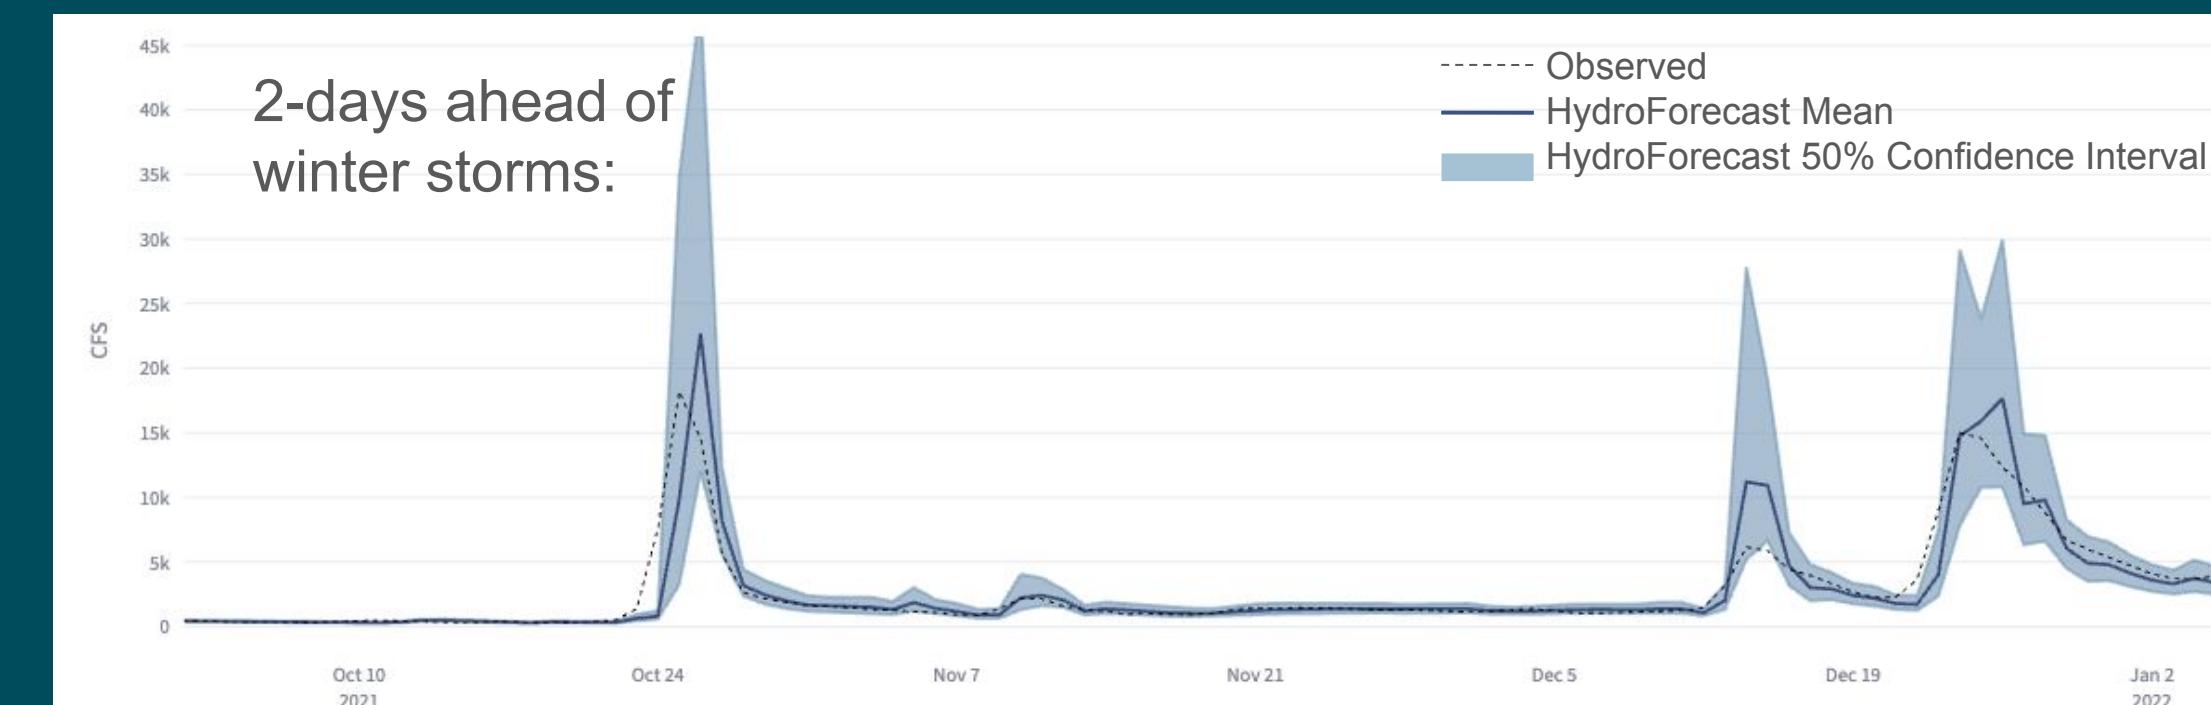

A fully operational hydrologic forecasting model that uses a machine learning core to predict hydrology, anywhere in the world.

HydroForecast predicts hourly flows out to 10 days, and daily flows out a year.

Highlights of the operational use cases included:

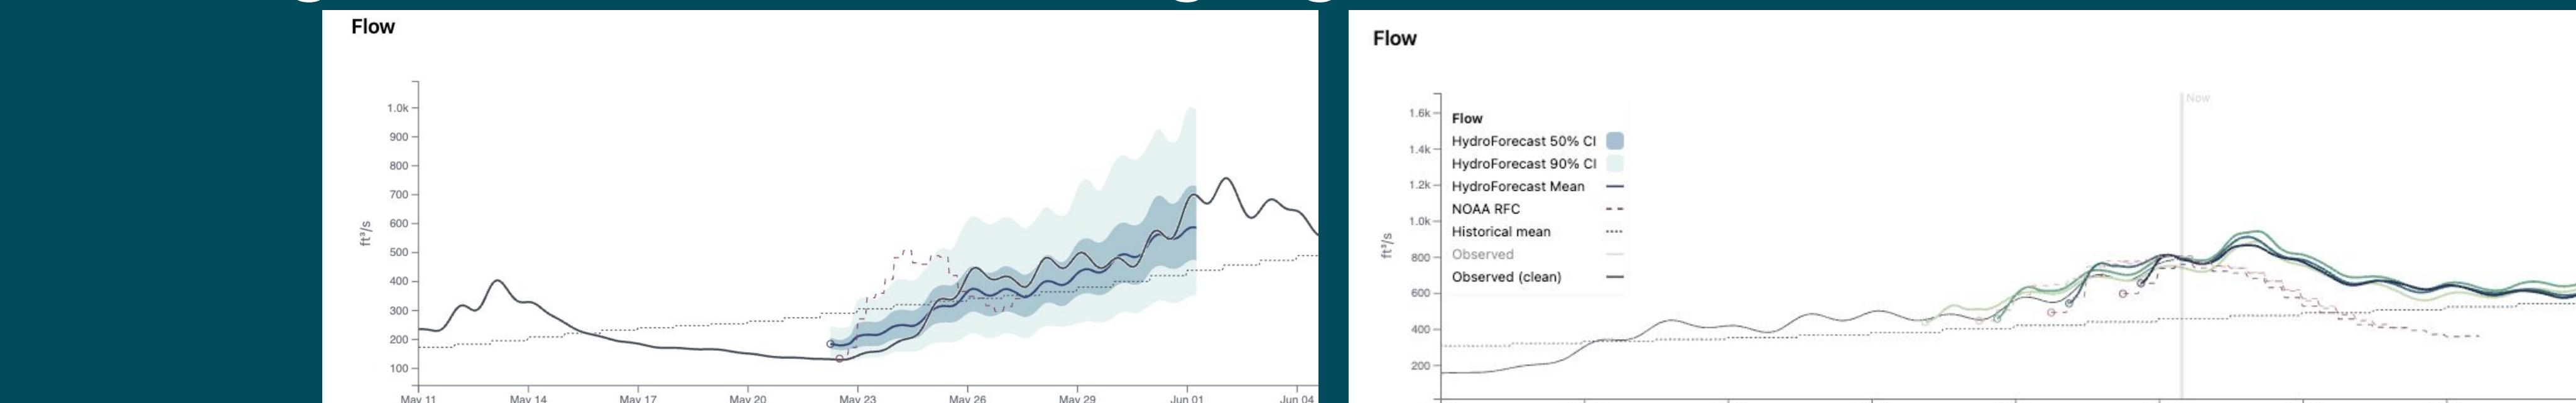

Flood control (aka FIRO operations)
e.g. at Folsom Lake, with upstream regulation:

Others!

- Water Supply Deliveries
- Environmental Flow Management
- Operations staff scheduling

Power generation and scheduling, e.g. Lake Estes, CO:

Weather generally agreed; temps were showing possible freezing
